Prof. Ben Kilminster

Standing sound waves in a closed tube of length L

Ruben's flame tube

Huygen's principle-

(b) Each point on a wavefront is a new point source.

(a) If $\Delta\phi = 90^\circ$, there is destructive interference.

(b) If $0^\circ < \Delta\phi < 90^\circ$, there is partial interference with amplitude $2A \cos \frac{\Delta\phi}{2}$.

(c) If $\Delta\phi = 0^\circ$, there is constructive interference with amplitude $2A$.

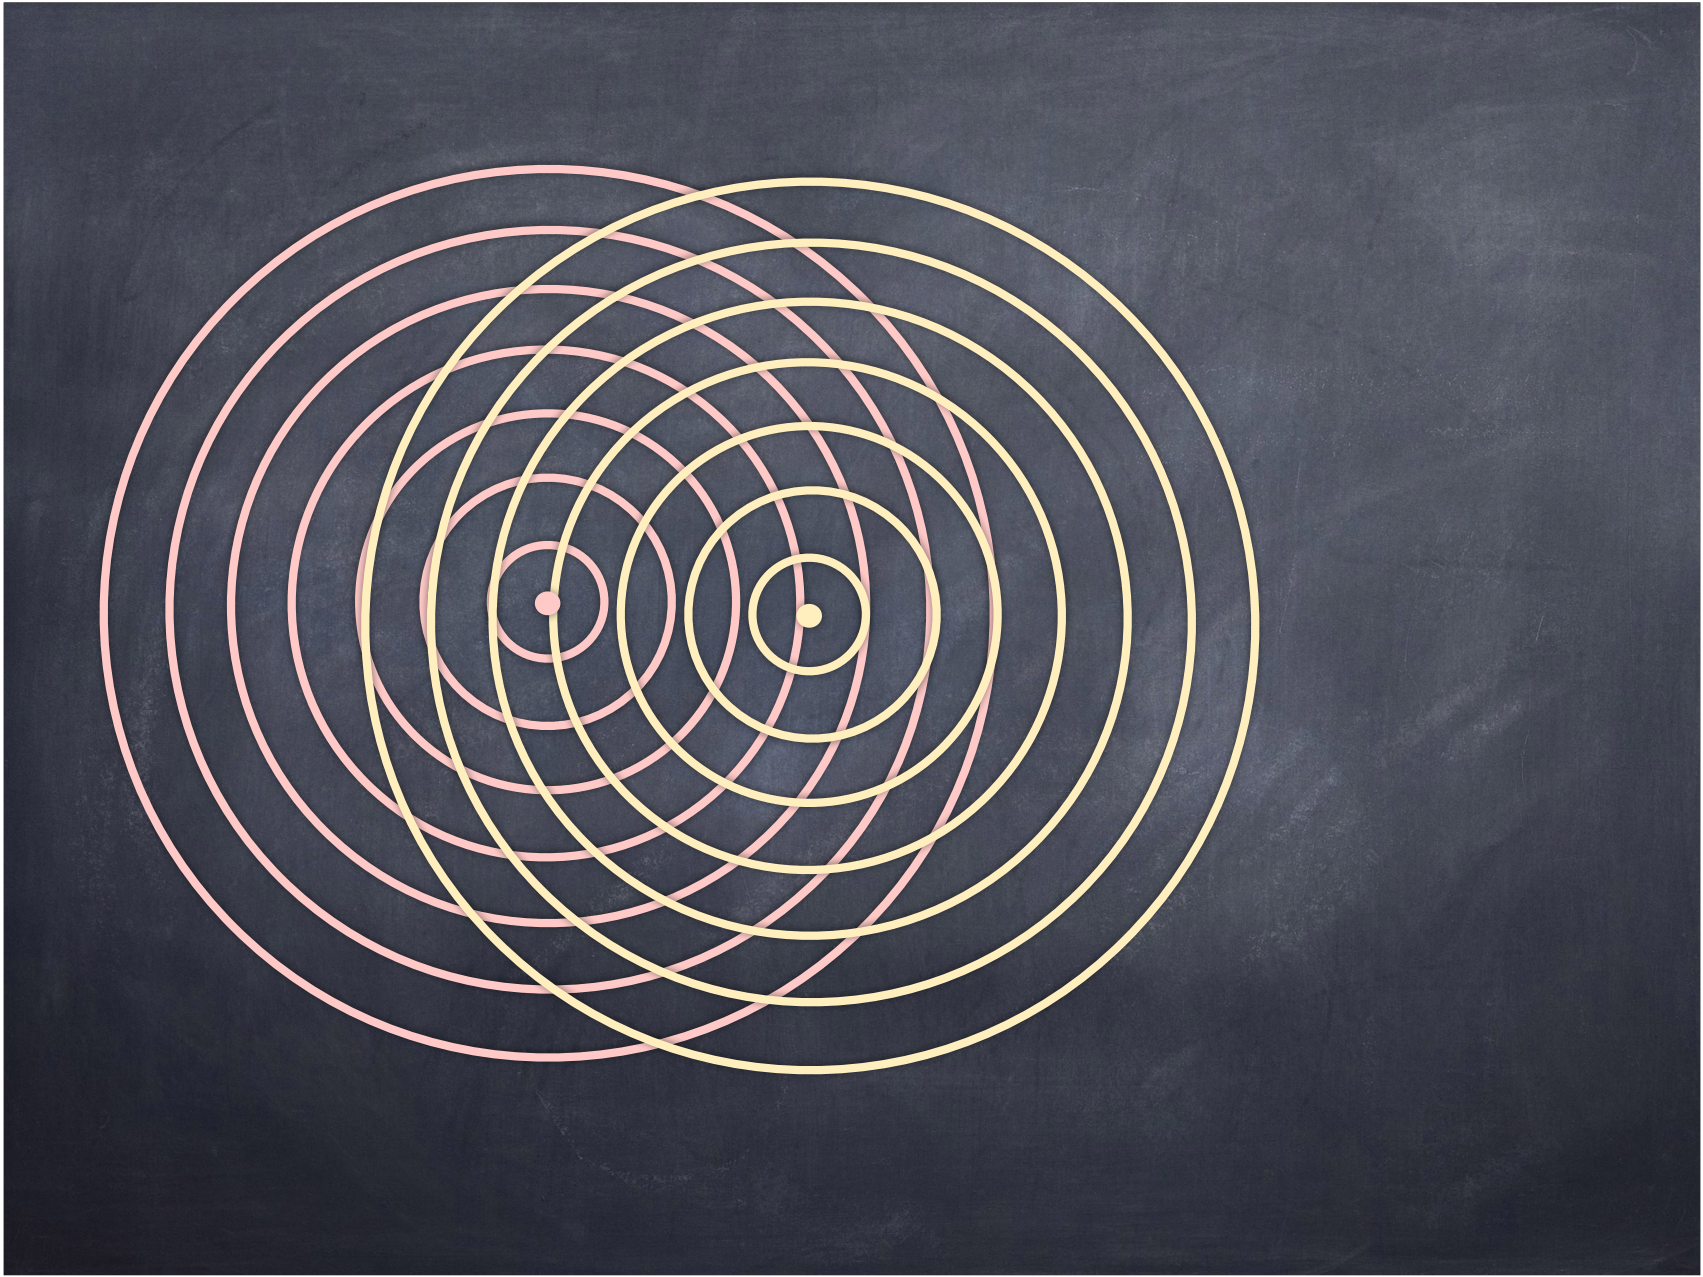

Figure 14.11: Interference between two waves with the same wavelength λ and amplitude A , but phase difference $\Delta\phi$.

2 sources coherently emitting waves

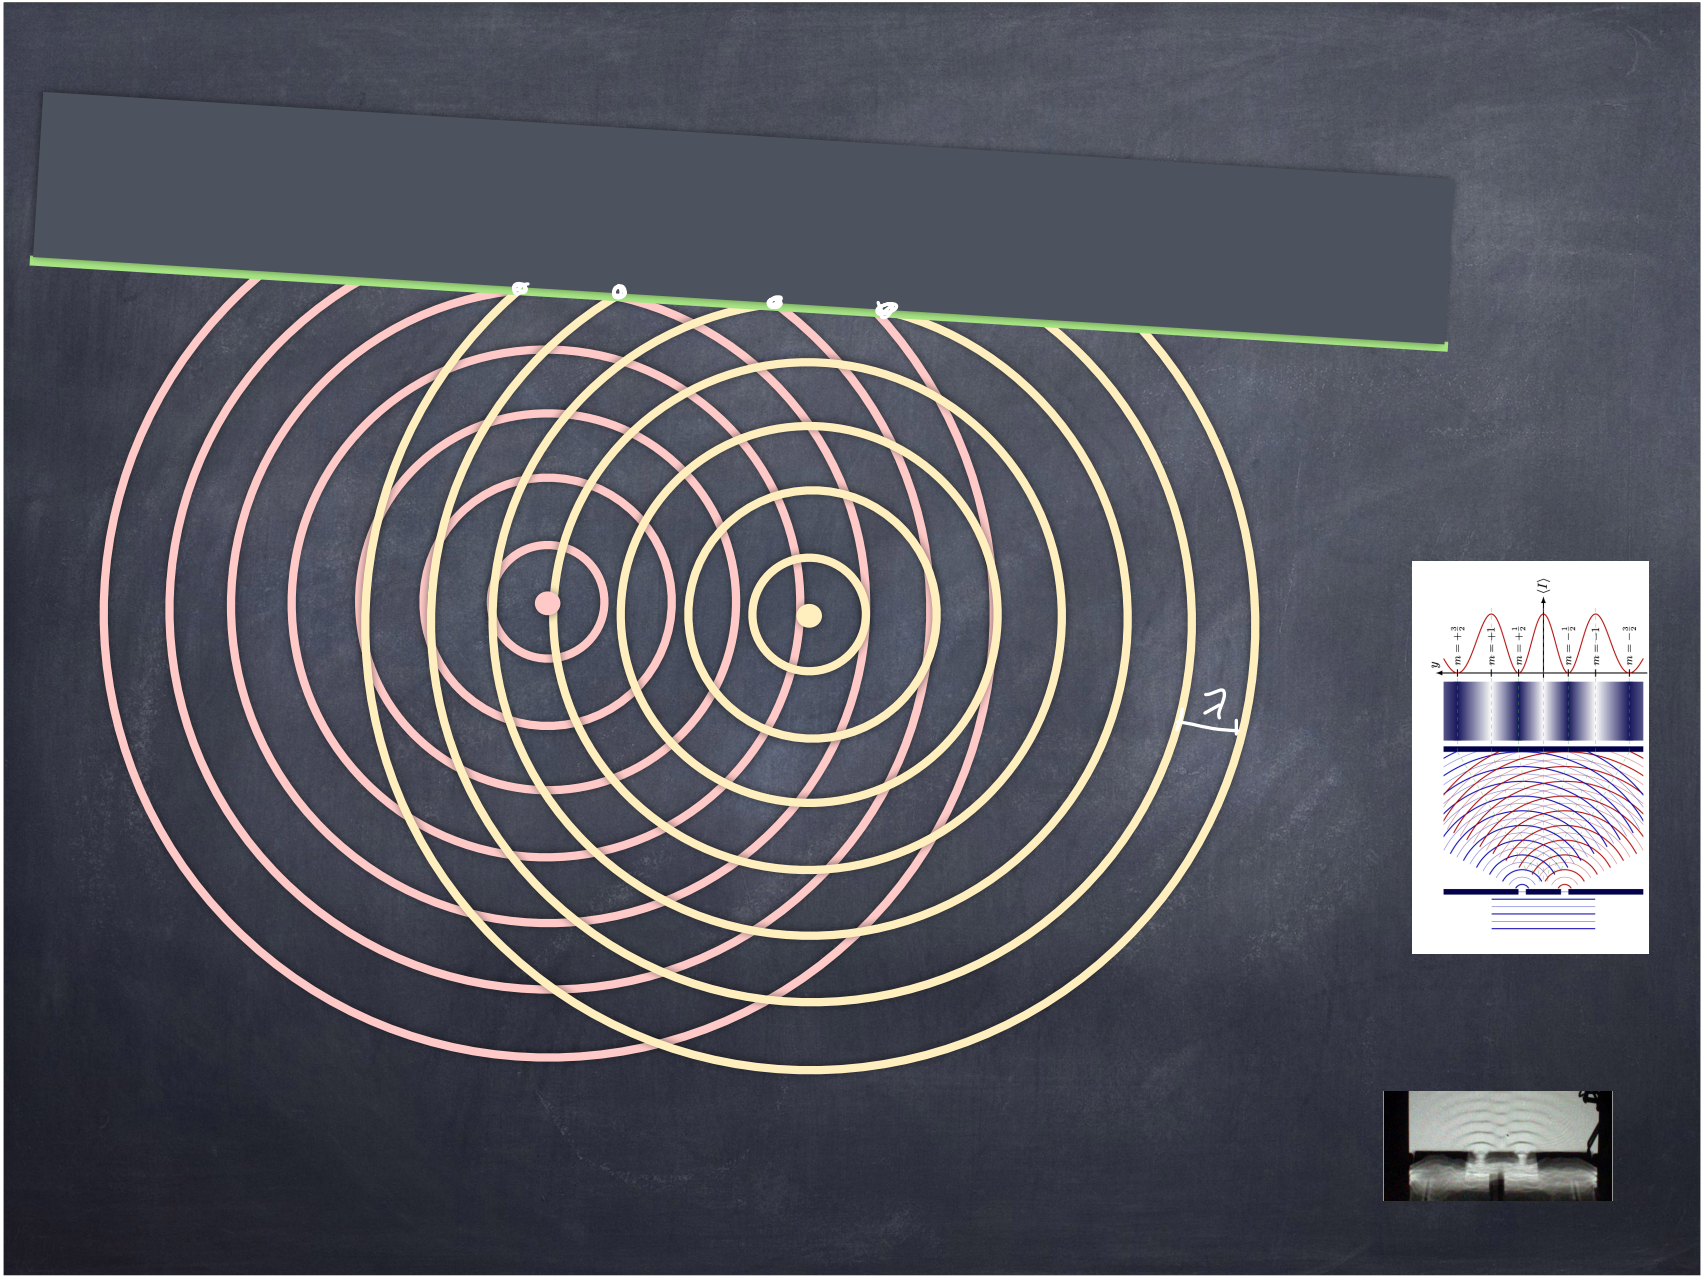

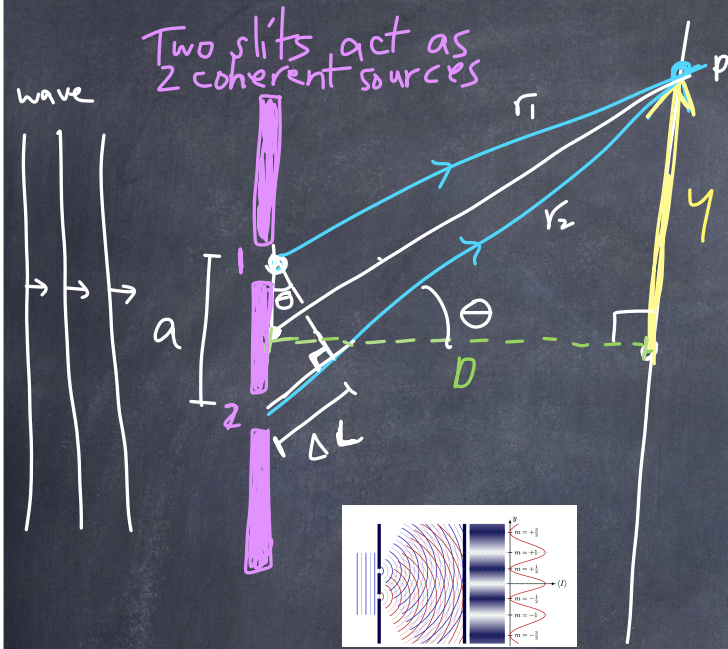

Along this line, the waves constructively interfere.

Ruben's flame tube - more understanding

$n=1$

oscillate

① ΔP ΔP is +

node

② ΔP

node

① → ② → ① ...

highest plane

$n=2$

① ΔP

node node

② ΔP

① → ② → ①

Extra!

For Ruben's flame tube:

For quiet sounds, ΔP of the gas $<$ P of the gas

Why is pressure higher at pressure nodes?

From Bernoulli's equation, gas flow is proportional to square root of the pressure difference between inside + outside tube.

$$\text{flow} \sim \sqrt{P_{\text{inside}} - P_{\text{outside}}}$$

(The flow of gas out of the pipe)

When $\Delta P_{\text{maximal}}$, anti-nodes produce lower flames (flow rate is lower)

When $\Delta P = 0$, nodes, flow rate is higher

Part of the cycle, pressure is higher than average but part is lower. On average

This is why pressure is higher at nodes:

$$\sqrt{P + \Delta P \text{ at anti-nodes}} < \sqrt{P + \Delta P \text{ at nodes}}$$
